

Site Day

Tape first, then Magicplan, then damage photos. Print and carry this. Priorities are already decided — do not improvise the order.

What today is actually for

This phone has **no LiDAR**, so it cannot produce the depth archives the pipeline consumes. Photos taken today **will not feed the reconstruction**. What today produces is the **Magicplan head-to-head comparison**, made defensible by tape-measuring the same rooms. That is the deliverable — do not spend the day on the 8-pass photo protocol instead.

Do this in the first 10 minutes, indoors

- ☐ Install Magicplan and confirm the free tier can **actually export a plan** (PDF, PNG or DXF)
- ☐ If it cannot, **screenshot the limit message** — that is itself the honest Part 3 finding
- ☐ Note the app version
- ☐ Clear phone storage, battery 100%, airplane mode **on**

THE THREE PRIORITIES

1 — TAPE 2 ROOMS, THEN MAGICPLAN THEM

the deliverable · ~70 min

Pick **living room** and **master bedroom**. If either has **no POP / false ceiling**, prefer it — otherwise ceiling height is ambiguous by 10–20 cm and the comparison is worthless. Tape each room **before** scanning it, then scan it. Full list on page 2.

2 — DAMAGE PHOTOS

only if damage exists · 15 min

Per item: **5 overlapping close shots** at 0.5–0.8 m in focus filling the frame, **1 wide shot** for context, and **a tape in frame** for scale. That last one is what makes it evidence rather than a snapshot.

3 — 8-PASS PHOTO SURVEY

low value today · optional

Only if you are well ahead. Nothing shipped consumes phone photos. If you do it, follow the printed capture protocol exactly — and remember **1.00 m and 1.80 m are distances from the wall**, the phone stays at **1.40 m**.

Skip entirely

Bathrooms, balcony, utility — mirror-heavy and lowest value per minute. Video (nothing consumes it yet). Chasing texture on blank painted walls.

Tape first

These numbers are what Magicplan will be judged against. If they are wrong, the comparison is worthless — so precision beats speed.

Technique — non-negotiable

- **Write the room name on the card before you measure.** Never measure an unnamed room.
- Record **millimetres**, not centimetres, with leading zeros: 1245 , not 1 245 .
- **Pull the tape taut and straight.** A sagging tape reads short, a twisted one reads long. Sight along it.
- **Read at eye level**, directly above the tape, never at an angle.
- **Measure every wall length twice**, independently, and write both numbers. If they differ by more than 5 mm, measure a third time and keep all three.
- Photograph the card after every five readings, filling the frame, so each number stays permanently linked to its room.

WHAT TO MEASURE, PER ROOM

WHAT	COUNT	HOW
Wall lengths, corner to corner at floor level	4 × 2	Both readings written. Label which wall each belongs to: “wall you face entering the door”, etc.
Ceiling height, floor to ceiling	3	Different parts of the room. State whether you measured to the POP ceiling or the slab.
Floor diagonal, corner to opposite corner	1	Catches a room that is not actually rectangular — the most common silent error.
Door widths	3 each	Top, middle and bottom — openings are often trapezoidal and that variation is real information. Plus door height.
Window widths	3 each	Top, middle, bottom. Plus sill height, floor to underside of sill.
Level changes	any	Steps, thresholds, split levels — and their height.
Total	~22	~30 min per room with two people

Measurement card — one per room	
Room name (written before measuring)	LIVING ROOM
Date	04 Oct
Wall lengths, both readings	4250 / 4248, 4180 / 4183, 3620 / 3618, 3640 / 3641 mm
Ceiling heights, 3 spots	2740, 2755, 2730 mm
Floor diagonal	5582 mm
Door widths (top/mid/bot) + height	905 / 900 / 902 mm, 2100 mm
Window widths (top/mid/bot) + sill	1450 / 1455 / 1448 mm, sill 900 mm
False / POP ceiling? which height measured?	NO POP — measured to slab
Mirrors and glass, located	1 mirror dining wall

Then Magicplan, then evidence

Scan the rooms you taped, and nothing else. A scan of an untaped room adds nothing, because there is nothing to check it against.

MAGICPLAN, PER ROOM

- ☐ Stand near the doorway first and take **one wide shot** for context
- ☐ Walk the perimeter **slowly**, one continuous sweep — do not stop and restart
- ☐ Sweep the **floor** and the **ceiling** separately, not only the walls
- ☐ Walk **through every doorway** into the next space; the opening width is the tightest measurement in the whole assessment
- ☐ Keep the phone **upright**, screen facing you, move your feet — do not wave it around
- ☐ Do one room to completion before starting the next

Export and evidence — do not skip

- **Export the plan** (PDF, PNG or DXF — whatever the tier allows) and save it **off the phone**. Cloud-only is a real risk of losing the day's work.
- **Screenshot every export-limit message**. "Free tier cannot export" is a legitimate, reportable Part 3 result and needs evidence.
- Note the **handicap plainly**: this phone has no LiDAR, so Magicplan ran its camera/SLAM path. State it wherever the numbers appear.
- Magicplan is **another estimate**, never ground truth. The tape is the reference.

Before you leave the flat — final 10 minutes

- ☐ Both tape cards photographed, **room name legible**
- ☐ Every tape number written in millimetres, wall lengths measured twice
- ☐ Magicplan exports for **both** rooms saved off the phone
- ☐ Export-limit screenshots saved
- ☐ Damage shots taken with a tape in frame, if any damage exists
- ☐ Nothing sent through WhatsApp, Instagram or any compressor
- ☐ Everything backed up to a second location

Cutoffs

Tape both rooms before scanning either. If you scan first and run out of time, the measurements never exist and the whole session is wasted.

Absolute stop when the site closes. A room measured but not scanned still yields a usable number; a room scanned but not measured yields nothing checkable. A declared gap costs far less than a rushed, broken capture.
